# Assignment 2

Kangrui Liu

9/28/2023

You may work in pairs or individually for this assignment. Make sure you join a group in Canvas if you are working in pairs. Turn in this assignment as an HTML or PDF file to ELMS. Make sure to include the R Markdown or Quarto file that was used to generate it.

In this assignment, you will pull from APIs to get data from various data sources and use your data wrangling skills to use them all together. You should turn in a report in PDF or HTML format that addresses all of the questions in this assignment, and describes the data that you pulled and analyzed. You do not need to include full introduction and conclusion sections like a full report, but you should make sure to answer the questions in paragraph form, and include all relevant tables and graphics.

Whenever possible, use piping and dplyr. Avoid hard-coding any numbers within the report as much as possible.

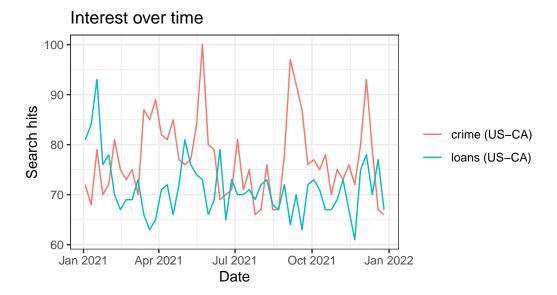

### 1. Git and GitHub

Provide the link to the GitHub repo for Assignment2.

• https://github.com/krliu67/Assignment\_SURV727/tree/main/a2 \*

## 2. Pulling from APIs

Our first data source is the Google Trends API. Suppose we are interested in the search trends for crime and loans in Caifornia in the year 2021. We could find this using the following code:

- 1) Answer the following questions for the keywords "crime" and "loans".
- a) Find the mean, median and variance of the search hits for the keywords.

```
res_ca_mmv <- res_ca$interest_over_time %>%
  group_by(keyword) %>%
  summarize(mean_hits=mean(hits), median_hits=median(hits), var_hits=var(hits))
res_ca_mmv
## # A tibble: 2 x 4
     keyword mean_hits median_hits var_hits
##
     <chr>>
                  <dbl>
                              <dbl>
                                        <dbl>
## 1 crime
                   77.1
                               76
                                        63.2
## 2 loans
                   71.3
                               70.5
                                        33.4
```

- According to the table presented above, the mean, median and variance of covid are 77.08, 76 and 63.17 separately. And, the mean, median and variance of shooting are 71.29,70.5 and 33.42 separately.
- b) Which cities (locations) have the highest search frequency for loans? Note that there might be multiple rows for each city if there were hits for both "crime" and "loans" in that city. It might be easier to answer this question if we had the search hits info for both search terms in two separate variables. That is, each row would represent a unique city.

```
# handle missing value
res_ca_city <- spread(na.omit(res_ca\$interest_by_city), key = keyword, value = hits)
# prevent some data was loaded as other types
res_ca_city\$crime <- as.numeric(res_ca_city\$crime)
res_ca_city\$loans <- as.numeric(res_ca_city\$loans)
res_ca_city[is.na(res_ca_city)] <- 0
head(res_ca_city)</pre>
```

```
geo gprop crime loans
##
        location
## 1
           Acton US-CA
                                         3
                          web
          Alpine US-CA
## 2
                                         3
## 3 Alta Sierra US-CA
                                   0
                                         2
                          web
## 4
        Altadena US-CA
                          web
                                  15
                                         0

                                   6
                                         0
                          web
## 6 Angels Camp US-CA
                                  13
                                         3
                          web
```

```
res_ca_city %>% subset(loans==max(res_ca_city$loans))
```

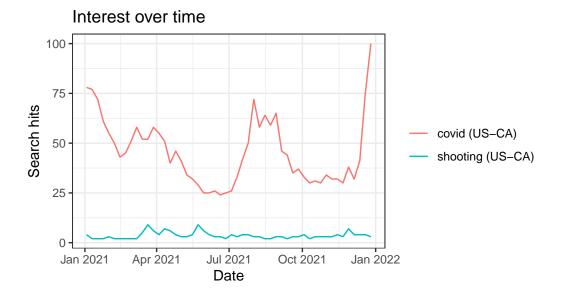

```
## location geo gprop crime loans
## 288 Yosemite Lakes US-CA web 4 100
```

- Yosemite Lakes has the highest search frequency for loans in 2021 in California.
- c) Is there a relationship between the search intensities between the two keywords we used?

```
cor_ca_city <- cor(res_ca_city$crime, res_ca_city$loans)
cor_ca_city</pre>
```

```
## [1] -0.07648137
```

- The correlation index of loans and crime in 2021 in California is -0.08, which means two keywords are weak negative linear correlated.
- d) Repeat the above for keywords related to covid. Make sure you use multiple keywords like we did above. Try several different combinations and think carefully about words that might make sense within this context.
- 2. Answer the following questions for the keywords "covid" and "shooting".

a) Find the mean, median and variance of the search hits for the keywords.

```
res1_ca_mmv <- res1_ca$interest_over_time %>%
  group_by(keyword) %>%
  summarize(mean_hits=mean(hits), median_hits=median(hits), var_hits=var(hits))
res1_ca_mmv
## # A tibble: 2 x 4
     keyword mean_hits median_hits var_hits
##
                                        <dbl>
##
     <chr>
                  <dbl>
                               <dbl>
## 1 covid
                  45.7
                                42.5
                                       286.
                                         2.79
## 2 shooting
                   3.60
                                 3
```

- According to the table presented above, the mean, median and variance of covid are 45.65, 42.5 and 286.19 separately. And, the mean, median and variance of shooting are 3.6, 3 and 2.79 separately.
- b) Which cities (locations) have the highest search frequency for covid and shooting? Note that there might be multiple rows for each city if there were hits for both "crime" and "loans" in that city. It might be easier to answer this question if we had the search hits info for both search terms in two separate variables. That is, each row would represent a unique city.

```
# handle missing value
res1_ca$interest_by_city <- na.omit(res1_ca$interest_by_city)

# handle 'multiple rows for each city'
temp <- res1_ca$interest_by_city %>% filter(keyword=="covid")
temp <- as.data.frame(table(temp$location)) %>% filter(Freq > 1)
# find the cities which has multiple rows in a keyword
names <- temp[,1]</pre>
```

```
rm(temp)
if (length(names) != 0){
  duplicate_rows <- res1_ca$interest_by_city %>% filter(keyword=="covid" & location==names)
  # keep the rows which keyword is not 'multiple rows for each city'
  temp <- subset(res1_ca$interest_by_city, keyword =="shooting")</pre>
  # keep the rows which keyword is but city don't have multiple rows
  res1 ca$interest by city <- subset(res1 ca$interest by city, keyword=="covid" & location!=names)
  # delete duplicate rows and add hits up to one row for each city
  duplicate_rows[1,2] = sum(duplicate_rows$hits)

## 90 El Cerrito US-CA
                          web
                                113
  • El Cerrito has the highest search frequency for covid in 2021 in California. And, Adelanto has the
    highest search frequency for shooting in 2021 in California.
     ### c) Is there a relationship between the search intensities between the two keywords we used?
cor1_ca_city <- cor(res1_ca_city$covid, res1_ca_city$shooting)</pre>
cor1_ca_city
```

## [1] -0.6474521

• The correlation index of covid and shooting in 2021 in California is -0.65', which means two keywords are negative linear correlated.

### 3. Google Trends + ACS

Now lets add another data set. The censusapi package provides a nice R interface for communicating with this API. However, before running queries we need an access key. This (easy) process can be completed here:

https://api.census.gov/data/key\_signup.html

Once you have an access key, store this key in the cs\_key object. We will use this object in all following API queries.

```
library(dplyr)
library(magrittr)
cs_key <- read.table("D:/suds/727/acs-key.txt")[1,1]</pre>
```

In the following, we request basic socio-demographic information (population, median age, median household income, income per capita) for cities and villages in the state of Illinois.

```
##

## 6
```

Convert values that represent missings to NAs.

```
acs_il[acs_il == -666666666] <- NA
```

Now, it might be useful to rename the socio-demographic variables (B01001\_001E etc.) in our data set and assign more meaningful names.

It seems like we could try to use this location information listed above to merge this data set with the Google Trends data. However, we first have to clean NAME so that it has the same structure as location in the search interest by city data. Add a new variable location to the ACS data that only includes city names.

```
# Clean Data
acs_ca <- getCensus(name = "acs/acs5",</pre>
                    vintage = 2021,
                    vars = c("NAME",
                              "B01001_001E",
                              "B06002_001E",
                              "B19013 001E",
                              "B19301_001E"),
                    region = "place:*",
                    regionin = "state:06",
                    key = cs_key
acs_ca[acs_ca == -666666666] <- NA
acs_ca <-
  acs_ca %>%

## 6 00394 Agoura Hills city California 20362 44.8
```

- I change the state to California, and transformed NAME into location and state by cutting comma.
- 1) Answer the following questions with the "crime" and "loans" Google trends data and the ACS data.
- a) First, check how many cities don't appear in both data sets, i.e. cannot be matched. Then, create a new data set by joining the Google Trends and the ACS data. Keep only cities that appear in both data sets.

```
library(stringr)
# clean data, if location contains CDP or city, delete
for (x in 1:dim(acs_ca)[1]) {
   temp <- acs_ca$location[x]
   if (str_detect(acs_ca$location[x],"CDP") == TRUE){
      temp <- gsub("CDP",'',temp)
   }
   if (str_detect(acs_ca$location[x],"city") == TRUE){
      temp <- gsub("city",'',temp)
   }
   temp <- trimws(temp)
   acs_ca$location[x] <- temp
}
rm(temp)</pre>
```

```
# find common cities in res1_ca_city and acs_ca
common_cities <- intersect(res_ca_city$location, acs_ca$location)
temp1 <- res_ca_city[res_ca_city$location %in% common_cities,]
temp2 <- acs_ca[acs_ca$location %in% common_cities,]
temp2_dup_names <- as.data.frame(table(temp2$location)) %>% filter(Freq > 1)
temp2_dup <- acs_ca[acs_ca$location %in% temp2_dup_names$Var1,]
temp2 <- temp2[!(temp2$location %in% temp2_dup$location),]
temp2_dup_names <- unique(temp2_dup$location)
# clean data and pre-process data</pre>
```

```
for (x in 1:length(temp2_dup_names)) {
  temp_rows <- temp2_dup[temp2_dup$location %in% temp2_dup_names[x],]
  temp_df <- data.frame(</pre>
    place=temp_rows$place[1],

• Due there have "CDP" and "city" in acs\_ca\$location, the common cities we intend to find will be difficult, so I delete these two dirty words inacs\_ca\$location. Then we can find common cities in acs\_ca and res\_ca\_city so that combining those cities to a new data. Considering that the age, hh\_income and income are Relative numbers, so I do computations of summing two rows up by proportion each pop of row has.

b) Compute the mean of the search popularity for both keywords for cities that have an above average median household income and for those that have an below average median household income. When building your pipe, start with creating the grouping variable and then proceed with the remaining tasks. What conclusions might you draw from this?

```
merged_df[is.na(merged_df)] <- 0

above_hh <- merged_df %>%
    filter(hh_income > mean(hh_income))%>%
    summarize(mean_crime_hits=mean(crime),mean_loans_hits=mean(loans))

below_hh <- merged_df %>%
    filter(hh_income <= mean(hh_income))%>%
    summarize(mean_crime_hits=mean(crime), mean_loans_hits=mean(loans))

above_hh;below_hh
```

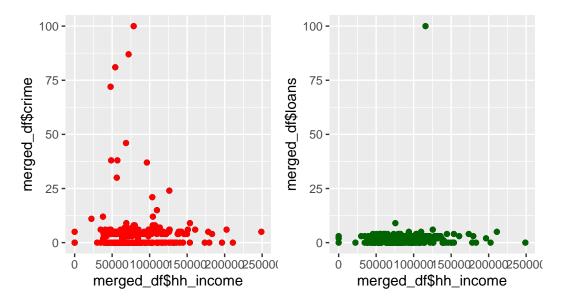

```
## mean_crime_hits mean_loans_hits
## 1 3.638889 2.509259

## mean_crime_hits mean_loans_hits
## 1 5.471698 1.679245
```

- There are 2 conclusions I draw from above tables. One is, In both subsets, the search frequency of crime is more than loans. Another is, Cities which have an below average median household income search both keywords more frequent than which have an above average median.
- c) Is there a relationship between the median household income and the search popularity of the Google trends terms? Describe the relationship and use a scatter plot with qplot().

```
library(ggplot2)
p1 <- qplot(x=merged_df$hh_income,y=merged_df$crime)+
    geom_point(color="red")
p2 <- qplot(x=merged_df$hh_income,y=merged_df$loans)+
    geom_point(color="darkgreen")

library(gridExtra)
library(grid)
grid.arrange(p1, p2, ncol = 2)</pre>
```

```
cor_hh_cr <- cor(merged_df$hh_income,merged_df$crime)
cor_hh_lo <-cor(merged_df$hh_income,merged_df$loans)
cor_hh_cr;cor_hh_lo</pre>
```

## [1] -0.05689854

## [1] 0.05425207

• According to plots, I found the distribution of points are chaos, and I guess that there is no clear relationship between the median household income and the search popularity of the Google trends terms. Observed from data, the correlation index of househould income and crime hits is -0.06. and the correlation index of househould income and loans hits is 0.05. In my view, both correlation index were close to 0.00, which had weak relationships.

#### 2. Repeat the above steps using the covid and shooting data and the ACS data.

a) First, check how many cities don't appear in both data sets, i.e. cannot be matched. Then, create a new data set by joining the Google Trends and the ACS data. Keep only cities that appear in both data sets.

```
# find common cities in res1_ca_city and acs_ca
common_cities1 <- intersect(res1_ca_city$location, acs_ca$location)
temp1 <- res1_ca_city[res1_ca_city$location %in% common_cities1,]
temp2 <- acs_ca[acs_ca$location %in% common_cities1,]
temp2_dup_names <- as.data.frame(table(temp2$location)) %>% filter(Freq > 1)
temp2_dup <- acs_ca[acs_ca$location %in% temp2_dup_names$Var1,]
temp2 <- temp2[!(temp2$location %in% temp2_dup$location),]
temp2_dup_names <- unique(temp2_dup$location)
# clean data and pre-process data
for (x in 1:length(temp2_dup_names)) {
   temp_rows <- temp2_dup[temp2_dup$location %in% temp2_dup_names[x],]</pre>
```

```
temp_df <- data.frame(</pre>
    place=temp_rows$place[1],
    location=temp2_dup_names[x],
    state=temp_rows$state[1],
    pop=sum(temp_rows$pop),
    age=(temp_rows$pop[1]*temp_rows$age[1]/sum(temp_rows$pop))+(temp_rows$pop[2]*temp_rows$age[2]/sum(t
    hh_income=(temp_rows$pop[1]*temp_rows$hh_income[1]/sum(temp_rows$pop))+(temp_rows$pop[2]*temp_rows$
    income=(temp_rows$pop[1]*temp_rows$income[1]/sum(temp_rows$pop))+(temp_rows$pop[2]*temp_rows$income
  )
  temp2 <- rbind(temp2,temp_df)</pre>
}
rm(temp_df)
rm(temp_rows)
rm(temp2_dup)
merged_df1 <- cbind(temp1,temp2,by = "location")</pre>
merged_df1 <- merged_df1[, !colnames(merged_df1) %in% "location.1"]</pre>
rm(temp1)
rm(temp2)
```

b) Compute the mean of the search popularity for both keywords for cities that have an above average median household income and for those that have an below average median household income. When building your pipe, start with creating the grouping variable and then proceed with the remaining tasks. What conclusions might you draw from this?

```
merged_df1[is.na(merged_df1)] <- 0

above_hh1 <- merged_df1 %>%
    filter(hh_income > mean(hh_income))%>%
    summarize(mean_covid_hits=mean(covid),mean_shooting_hits=mean(shooting))
below_hh1 <- merged_df1 %>%
    filter(hh_income <= mean(hh_income))%>%
    summarize(mean_covid_hits=mean(covid), mean_shooting_hits=mean(shooting))
above_hh1;below_hh1
```

```
## mean_covid_hits mean_shooting_hits
## 1 30.93798 27.5814

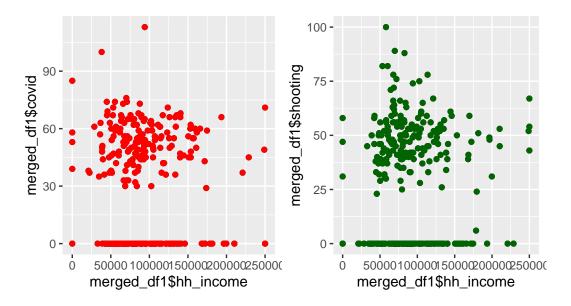

## mean_covid_hits mean_shooting_hits
## 1 30.09524 28.28571
```

• Also, there are 2 conclusions I draw from above tables. A is, In both subsets, the search frequency of covid is more than shooting. B is, Cities which have below average median household income search shooting keyword more frequent than which have an above average median, whereas families which had more wealth paid more attentions to covid rather than shooting.

c) Is there a relationship between the median household income and the search popularity of the Google trends terms? Describe the relationship and use a scatter plot with qplot().

```
library(ggplot2)
